

## SUMMARY OF ISONIAZID AND RIFAMPIN (3HR) FOR TREATMENT OF LATENT TB INFECTION (LTBI)

The following information is provided as a summary of current guidelines and should not be used as a substitute for review of current treatment recommendations including the following:

**Guidelines for the Treatment of Latent Tuberculosis Infection: Recommendations from the National Tuberculosis Controllers Association and CDC, 2020**

<https://www.cdc.gov/mmwr/volumes/69/rr/pdfs/rr6901a1-H.pdf>

- **3HR Therapy:** The recommended regimen is Isoniazid (INH) and Rifampin (RIF) daily for 3 months.

Daily INH	Adults	5 mg/kg daily	300 mg maximum dose
	Children	10-15 mg/kg daily	300 mg maximum dose
Daily Rifampin	Adults	10 mg/kg daily	600 mg maximum dose
	Children	15-20 mg/kg daily	600 mg maximum dose

- **Medication Formulation:** INH is formulated into 100 mg and 300 mg tablets. Rifampin is formulated into 150 mg and 300 mg capsules.
- **Adverse reactions** Rash, hepatic enzyme elevation, hepatitis, hypersensitivity reactions, peripheral neuropathy, mild CNS changes, optic neuritis, arthralgias, drug induced lupus and drug interactions (i.e. Dilantin, Tegretol, oral birth control, Methadone), pruritus, GI upset flu-like symptoms, hepatotoxicity, hematologic abnormalities (thrombocytopenia, hemolytic anemia) and orange staining of body fluids and soft contact lenses.
- **Clinical monitoring:** All patients receiving treatment for LTBI should be seen in person by healthcare personnel at least monthly. Clinical monitoring is the most effective strategy for reducing drug toxicity and is an essential element in all LTBI treatment regimens, regardless of other monitoring efforts. Clinical evaluations during LTBI treatment should assess for: adverse drug reactions, especially hepatotoxicity, adherence to therapy, signs and symptoms concerning for active TB disease and the need for continued patient education.
- **Baseline laboratory evaluation:** Baseline complete blood count (CBC) and serum creatinine should be obtained in patients who will be treated with 3HR. The following patients with an elevated risk of hepatotoxicity should receive baseline liver function tests (LFT's): pre-existing liver disease, history of alcohol abuse, HIV infection, concurrent treatment with other hepatotoxic medications, current or recent pregnancy (within 3 months of delivery) and individuals who were born in areas with high rates of viral hepatitis (e.g. countries in Asia and Africa). Testing should be considered on an individual basis.
- **Laboratory monitoring during treatment** Routine LFT's during LTBI treatment is not necessary for most patients. However, serial LFT's (at least monthly) should be obtained in the following circumstances: history of liver disease, alcohol use or concomitant use of other potential hepatotoxic drugs, pregnancy and abnormal baseline LFT's. In addition to LFT's, patients treated with 3HR who have lab abnormalities identified on baseline testing are recommended to have periodic CBC checks during therapy. Decisions regarding the frequency of testing and threshold for discontinuation of 3HR are individualized. Indications to stop LTBI treatment due to drug induced liver injury include transaminases  $\geq 5$  times normal in an asymptomatic patient, transaminases  $\geq 3$  times normal in a symptomatic patient or total bilirubin  $\geq 2$ .
- **Completion criteria for 3HR therapy:** Completion of therapy is based on the total number of doses administered, not duration of therapy alone.

Daily INH & Rifampin (3HR)	3 months	90 daily doses completed within 4 months
